

# Calibration of the Neural Network PiCAP (Protein Interaction of CARbohydrates Predictor)

Sho Takeshita

Gray Lab

3.14.2025

JOHNS HOPKINS  
UNIVERSITY

# Sam developed an algorithm to predict whether proteins bind to carbohydrates or not

# Calibration is a technique that smooths binary classifications to a scalar distribution

- PBind does not reflect true positive rate
- If there are 100 predictions of .8 predicted PBind, 80 of the predictions should be true
- Reduces difference between TP rate and predicted PBind

# Types of Calibration

---

- Regularization methods
- Post-hoc Methods
- Uncertainty Estimation

# Regularization Using Dice++

$$\mathcal{L}_{Dice} = 1 - \frac{2TP}{2TP + FP + FN} \rightarrow \mathcal{L}_{Dice++} = 1 - \frac{2TP}{2TP + (FP)^\gamma + (FN)^\gamma}$$

- Emphasizes greater loss when FP and FN are greater by adding  $\gamma$  hyperparameter

# Regularization Using Focal loss

Puts more focus on  
hard, misclassified data

# Post-hoc Calibration with Isotonic Regression

Fits monotonically increasing function to True Probabilities vs. Raw Predictions on secondary training set

$$\min \sum_{i=1}^n w_i (\hat{y}_i - y_i)^2$$

$$\hat{y}_i \leq \hat{y}_j \text{ for all } (i, j) \in E$$

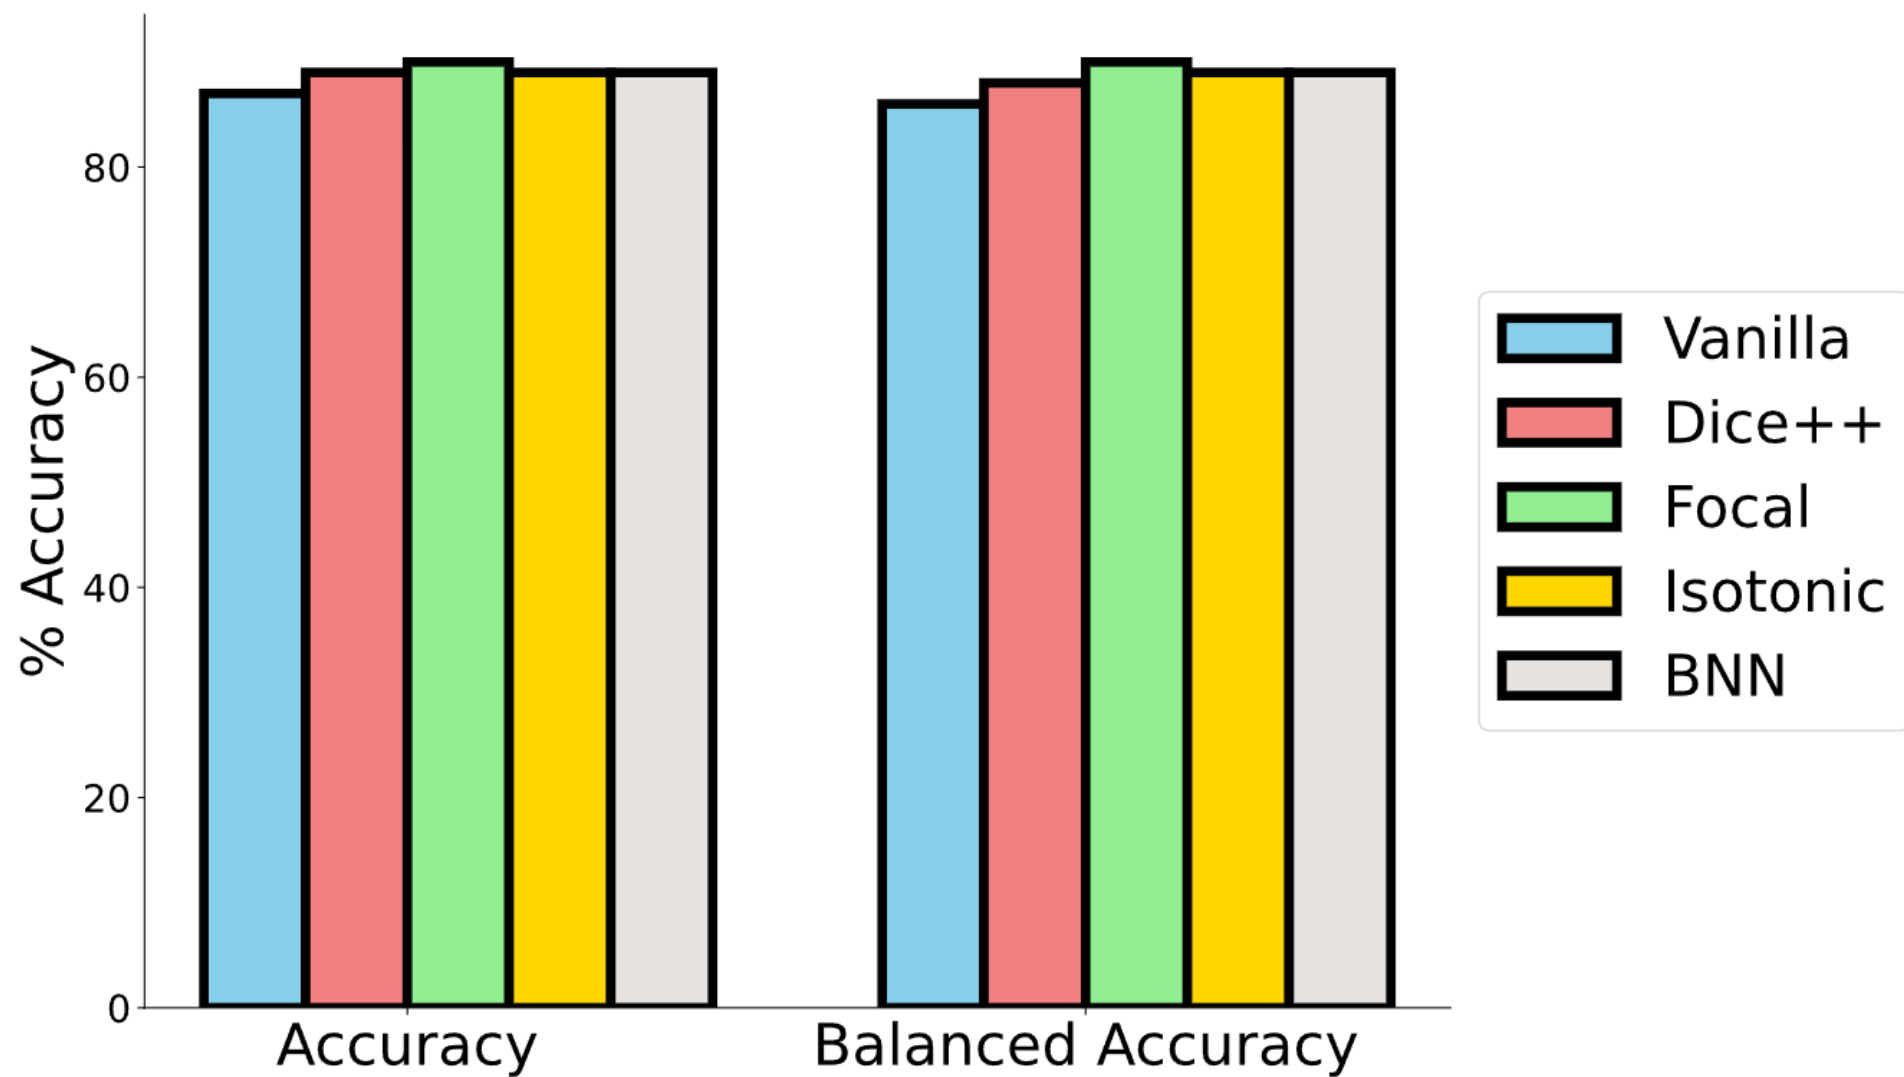

# Uncertainty Estimation with Bayesian Neural Network (BNN)

- Learns a gaussian distribution for weights instead of 1 scalar value
- During inference samples from distribution
- Can quantify uncertainty

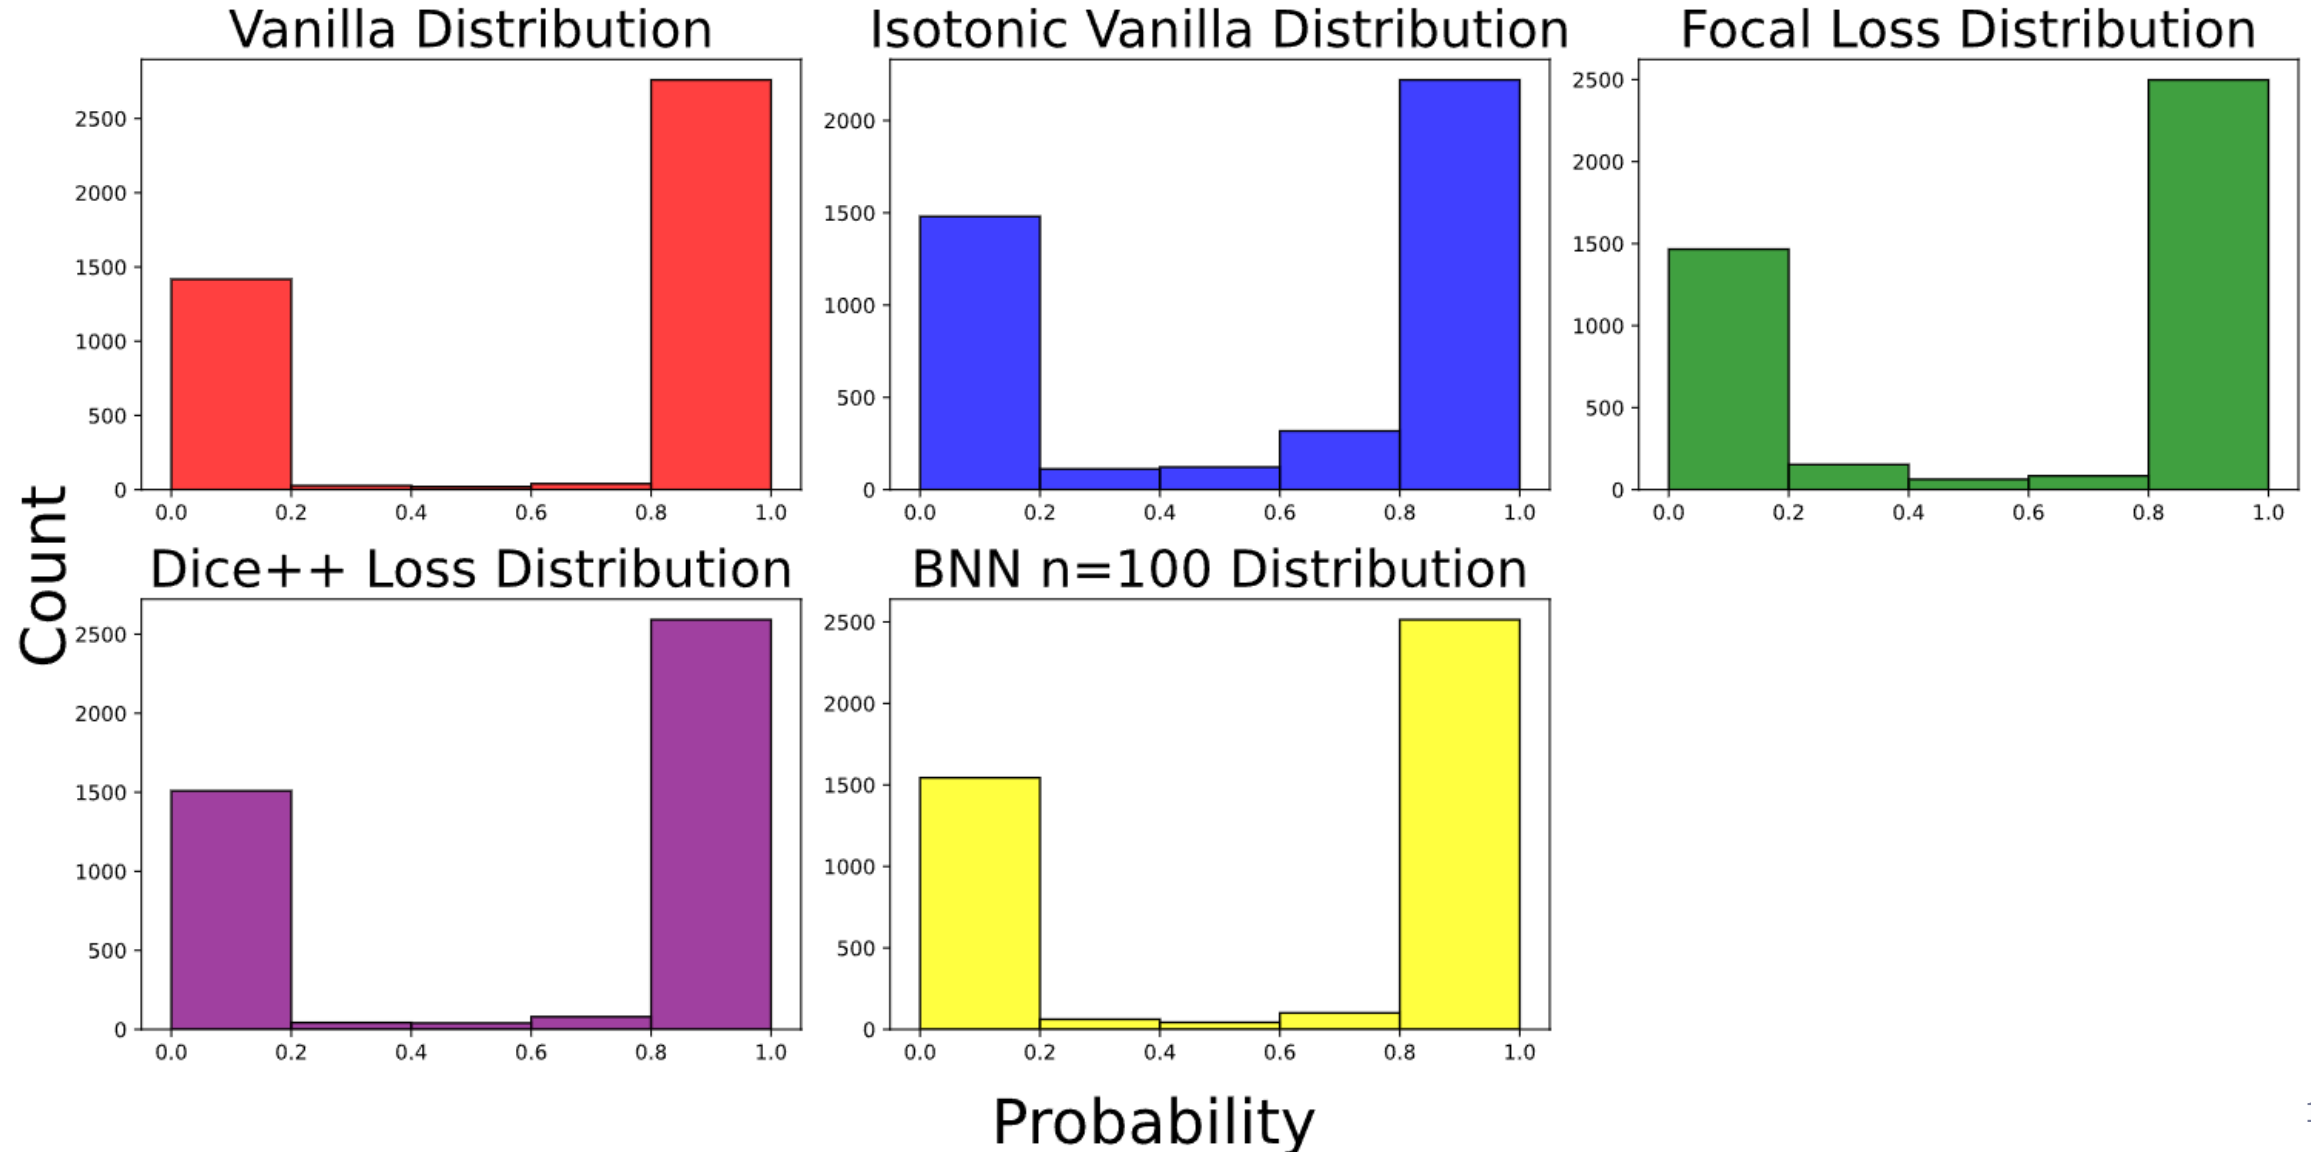

# Accuracies

# Calibration shifts the distributions

# Metrics

$$\text{acc}(b_m) = \frac{1}{|b_m|} \sum_{i \in B_m} \mathbf{1}(\hat{y}_i = y_i), \quad \text{conf}(b_m) = \frac{1}{|b_m|} \sum_{i \in B_m} p_i.$$

---

## Maximum Calibration Error

$$\text{MCE} = \max_{m \in \{1, \dots, M\}} |\text{acc}(b_m) - \text{conf}(b_m)|$$

## Expected Calibration Error

$$\text{ECE} = \frac{1}{N} \sum_{m=1}^M |b_m| |\text{acc}(b_m) - \text{conf}(b_m)|$$

## Classwise Expected Calibration Error

$$\text{CECE} = \sum_{m=1}^M \sum_{c=1}^K \frac{|b_{m,c}|}{NK} |\text{acc}_c(b_{m,c}) - \text{conf}_c(b_{m,c})|$$

# Reliability Diagram

- Gives a sense of how calibrated the model is
- Dashed line represents perfect calibration
- Red bars represent gap to perfect calibration

Binder

PBind=.77

Maltose Binder

# Thoughts and Conclusions

---

- Later in the training cycle, the more dramatic the effects are on model calibration
- Isotonic regression may be the way to go
- Still needs improvement

# Vanilla PiCAP

- Pre-training: Dice loss
- Fine-tuning: Binary Cross Entropy (BCE) loss

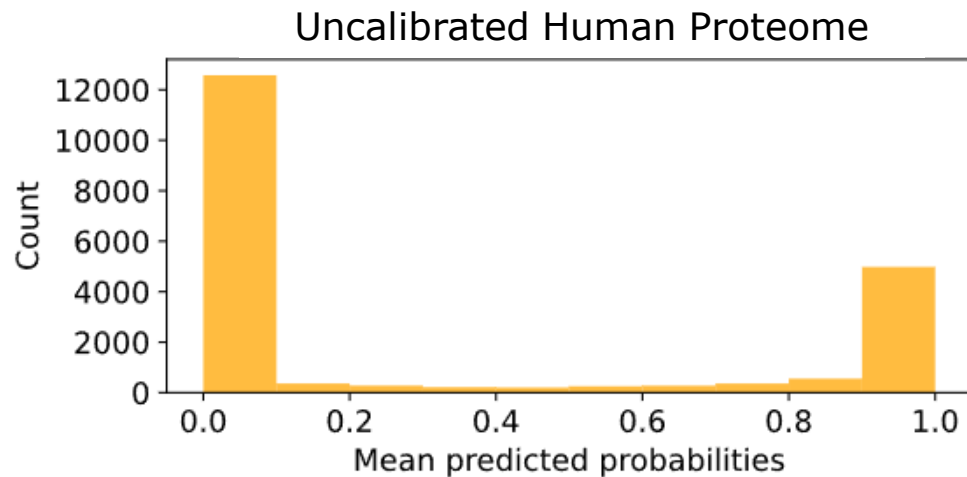

$$\mathcal{L}_{Dice} = 1 - \frac{2TP}{2TP + FP + FN}$$

$$\mathcal{L}_{BCE} = -\log(P_t)$$

$P_t$  = probability of predicting the ground truth class

# Calibration is a technique that smooths binary classifications to a scalar distribution

- Predictions reflect confidence
- If there are 100 predictions of .8 probability, 80 of the predictions should be true
- Prevents over-fitting and smooths distribution

## Human Proteome Predictions
